## Abstract

A set  $S \subset \mathbb{Z}^d$  is digital convex if  $\text{conv}(S) \cap \mathbb{Z}^d = S$ , where  $\text{conv}(S)$  denotes the convex hull of  $S$ . In this paper, we consider the algorithmic problem of testing whether a given set  $S$  of  $n$  lattice points is digital convex. Although convex hull computation requires  $\Omega(n \log n)$  time even for dimension  $d = 2$ , we provide an algorithm for testing the digital convexity of  $S \subset \mathbb{Z}^2$  in  $O(n + h \log r)$  time, where  $h$  is the number of edges of the convex hull and  $r$  is the diameter of  $S$ . This main result is obtained by proving that if  $S$  is digital convex, then the well-known quickhull algorithm computes the convex hull of  $S$  in linear time. In fixed dimension  $d$ , we present the first polynomial algorithm to test digital convexity, as well as a simpler and more practical algorithm whose running time may not be polynomial in  $n$  for certain inputs.
